#### Problem 5

- a) Suppose 0 ≤ x<sub>1</sub> < x<sub>2</sub>. Then x<sub>2</sub> = x<sub>1</sub> + k for a positive constant k. Then f(x<sub>2</sub>) = (x<sub>1</sub> + k)<sup>2</sup> = x<sub>1</sub><sup>2</sup> + 2kx<sub>1</sub> + k<sup>2</sup>. The product and the sum of two positive numbers are positive numbers, hence 2kx<sub>1</sub> + k<sup>2</sup> is a positive number. Then f(x<sub>1</sub>) = x<sub>1</sub><sup>2</sup> < x<sub>1</sub><sup>2</sup> + 2kx<sub>1</sub> + k<sup>2</sup> = f(x<sub>2</sub>) and f(x) = x<sup>2</sup> for x ≥ 0 is strictly increasing.
   b) We divide each side of the inequality x<sub>1</sub> < x<sub>2</sub> with the positive number x<sub>2</sub> and get the inequality
- b) We divide each side of the inequality  $x_1 < x_2$  with the positive number  $x_2$  and get the inequality  $\frac{x_1}{x_2} < 1$ . The square root of a number which is less than 1 is itself less than 1, i.e.  $\sqrt{\frac{x_1}{x_2}} < 1$ . But  $\sqrt{\frac{x_1}{x_2}} = \frac{\sqrt{x_1}}{\sqrt{x_2}}$ . We get the inequality  $\frac{\sqrt{x_1}}{\sqrt{x_2}} < 1$  and when we multiply each side with the positive number  $\sqrt{x_2}$  we get the inequality  $f(x_1) = \sqrt{x_1} < \sqrt{x_2} = f(x_2)$ . Hence  $f(x) = \sqrt{x}$  is strictly increasing.
- c) We divide each side of the inequality  $x_1 < x_2$  with the positive number  $x_2$  and get the equivalent inequality  $\frac{x_1}{x_2} < 1$ . Then we divide this inequality by the positive number  $x_1$  and get  $f(x_2) = \frac{1}{x_2} < \frac{1}{x_1} = f(x_1)$ . Hence  $f(x) = \frac{1}{x_1}$  for x > 0 is strictly decreasing.

b)

$$h(x) = \frac{x^{5}}{10} - \frac{3x^{4}}{2} + \frac{17x^{3}}{2} - \frac{45x^{2}}{2} + \frac{137x}{5} - 10$$

$$i(x) = x^{4} - 8x^{3} + 24x^{2} - 32x + \frac{161}{10}$$
